Appearance of Bruise

Lyme Rash

The CDC purports that a "Bulls-eye" EM Rash is the prime indicator of Lyme disease. However, in a recent study of over 6000 Lyme patients, only 17% had a bulls-eye rash, while 21% showed other rashes. The rash can be very small or very large, can imitate hives, eczema, sunburn, poison ivy, fleabites, etc. It can disappear and return later. It can itch or feel hot or not be felt at all.

On darker skin, it may look like a bruise.
